

Copilot

Sure, let me explain it in a simpler way.

In a Java project, you typically have two main directories:

1. **src/main/java**: This is where you write the actual code for your application. For a Selenium project, this would include your Page Objects, utility classes, and any other classes that make up your application.
2. **src/test/java**: This is where you write your test cases. These are scripts that test the functionality of your application. In a Selenium project, these would be your test scripts that interact with the web browser, using the Page Objects and utility classes from `src/main/java`.

So, in summary, `src/main/java` is for your application code, and `src/test/java` is for your test code. The two are kept separate to keep your project organized and to make sure that your application doesn't accidentally include test code. I hope this helps! Let me know if you have any other questions. 😊
